# ATI 2017 <br> Exercises on Interferometers 

M.A. Kenworthy

November 2017

1. The VLT interferometer has four telescopes, with the longest baseline between two of the 8.4 m telescopes being 144 m . To compensate for optical path differences introduced by the telescopes, there is a beam delay room underneath the mountain where the optical beam from each telescope is sent to a movable mirror retroreflector and sent back to the beam combination optics.
(a) What is the declination of the celestial object with the fastest apparent angular velocity on the celestial sphere, ignoring proper motions?
(b) What is the fastest speed that the retroreflector has to move when observing with the longest baseline?
2. The ALMA telescope is observing a galaxy at a wavelength of 0.7 mm , with the largest
possible baseline of 16 km and a shortest baseline of 150 m . The larger dishes used are

The ALMA telescope is observing a galaxy at a wavelength of 0.7 mm , with the largest
possible baseline of 16 km and a shortest baseline of 150 m . The larger dishes used are 12 m in diameter.
(a) Give the field of view and highest angular resolution of the observations.
(b) The lowest elevation for a celestial target is 25 degrees above the horizon. What is the largest time delay that the correlator has to introduce into the signals from the array to phase them?
3. Seven of the 12 m ALMA telescopes are placed in a line, with 36 m from the center of one dish to the center of the next dish in line.
(a) What is the approximate height of the first sidelobe of the PSF compared to the central on-axis lobe in the line of the interferometers? Normalise the height of the central peak of the PSF to be 1 .
(b) What is the relative height of the first grating peak to the normalised central PSF peak?
