

Astronomical Observing Techniques

Lecture 11: How to Fingerprint a Star

Christoph U. Keller

keller@strw.leidenuniv.nl

Overview

1. Spectral Lines
2. Spectrograph Concept
3. Grating Spectrograph
4. Grisms
5. Filters and Fabry-Perots
6. OH Suppression Spectrographs
7. Multi-Object Spectrographs
8. Fourier Transform Spectrometer

Fraunhofer's Solar Spectrum

A: telluric O₂

B: telluric O₂

C: H α

D: Na I D₁, D₂, He I D₃

E: Fe I

F: H β

G: CN band

H: Ca II

K: Ca II

Continuous, Emission, Absorption Spectra

The Sun in Helium I

Spectrograph Components

1. **Slit:** reduce telescope image to one dimension
2. **Collimator:** collimate (make parallel) diverging light
3. **Disperser:** spectrally disperses the light
4. **Camera:** focus spectrum onto detector

Long Slit Spectrum

Spectrograph Characteristics

- Spectral resolution element: $\Delta\lambda$
 - smallest spectral feature that can be resolved
 - FWHM of line that is not resolved
 - not the same as pixel size
- Spectral resolution (or resolving power) R:
$$R = \lambda / \Delta\lambda$$
 - $R < 100$: low spectral resolution
 - $R \approx 100 - 10'000$: medium spectral resolution
 - $R > 10'000$: high spectral resolution

Spectrograph Characteristics

- **Instrumental profile** $P(\lambda)$ broadens theoretically infinitely narrow line to observed line width:

$$I_0(\lambda) = \delta(\lambda - \lambda_0) \quad I(\lambda) = P(\lambda) * I_0(\lambda)$$

- *Instrumental profile often determines spectral resolution element, which should be Nyquist-sampled*
- **Transmission** determines throughput

$$\eta(\lambda) = \frac{I_{out}(\lambda)}{I_{in}(\lambda)}$$

Spectral Resolution and S/N

For unresolved spectral lines, both the S/N and the line/continuum contrast increase with increasing resolution

Model spectra of C_2H_2 at 900K and HCN at 600K (assumed Doppler broadening ~ 4 km/s) at different spectrograph resolutions (figure provided by F. Lahuis).

Prism

$$\frac{\partial \delta}{\partial \lambda} = \frac{\sin \alpha}{\cos \theta_o \cos \theta'_i} \cdot \frac{\partial n}{\partial \lambda} \quad \sin \theta'_i = \frac{\sin \theta_i}{n} \quad \sin \theta_o = n \sin(\alpha - \theta'_i)$$

- good for low-resolution spectroscopy
- no order overlap
- dispersion depends on wavelength

Angular Dispersion

- angular dispersion $d\delta/d\lambda$ maximized with high-dispersion $dn/d\lambda$ glass

$$\frac{\partial \delta}{\partial \lambda} = \frac{\sin \alpha}{\cos \theta_o \cos \theta'_i} \cdot \frac{\partial n}{\partial \lambda}$$

Diffraction Grating

Grating introduces optical path difference = $d \cdot \sin(\theta)$

Condition for constructive interference given by **grating equation**:

$$m\lambda = d \cdot (\sin \alpha \pm \sin \beta)$$

m = order of diffraction

λ = wavelength

d = distance between equally spaced grooves

α = angle of incoming beam

β = angle of reflected beam

Grating Spectral Resolution

- Grating equation $m\lambda = d \cdot (\sin \alpha \pm \sin \beta)$
- Gratings usually in **collimated beam** close to pupil image
- **Maximum spectral resolution R given by $R=mN$**
 N = number of (illuminated) grooves
 m = diffraction order
- **Angular dispersion** $d\beta / d\lambda = \frac{m}{d \cos \beta}$

Blaze Angle

- Periodic structure distributes energy over many orders
- Observing only one arbitrary order is inefficient
- For **blazed gratings** the *directions of constructive interference and specular reflection coincide*:

$$\alpha + \beta = 2(\alpha + \theta_B) \quad \Rightarrow \quad \theta_B = \frac{\beta - \alpha}{2}$$

Advantage:

- High efficiency

Disadvantage:

- Blaze angle θ_B (and blaze wavelength λ_B) fixed by construction

Free Spectral Range

A light bulb seen through a transmissive grating, showing three diffracted orders. $m = 0$ corresponds to direct transmission; colors with increasing wavelengths (from blue to red) are diffracted at increasing angles. Source: Wikipedia

Different diffraction orders overlap with each other:

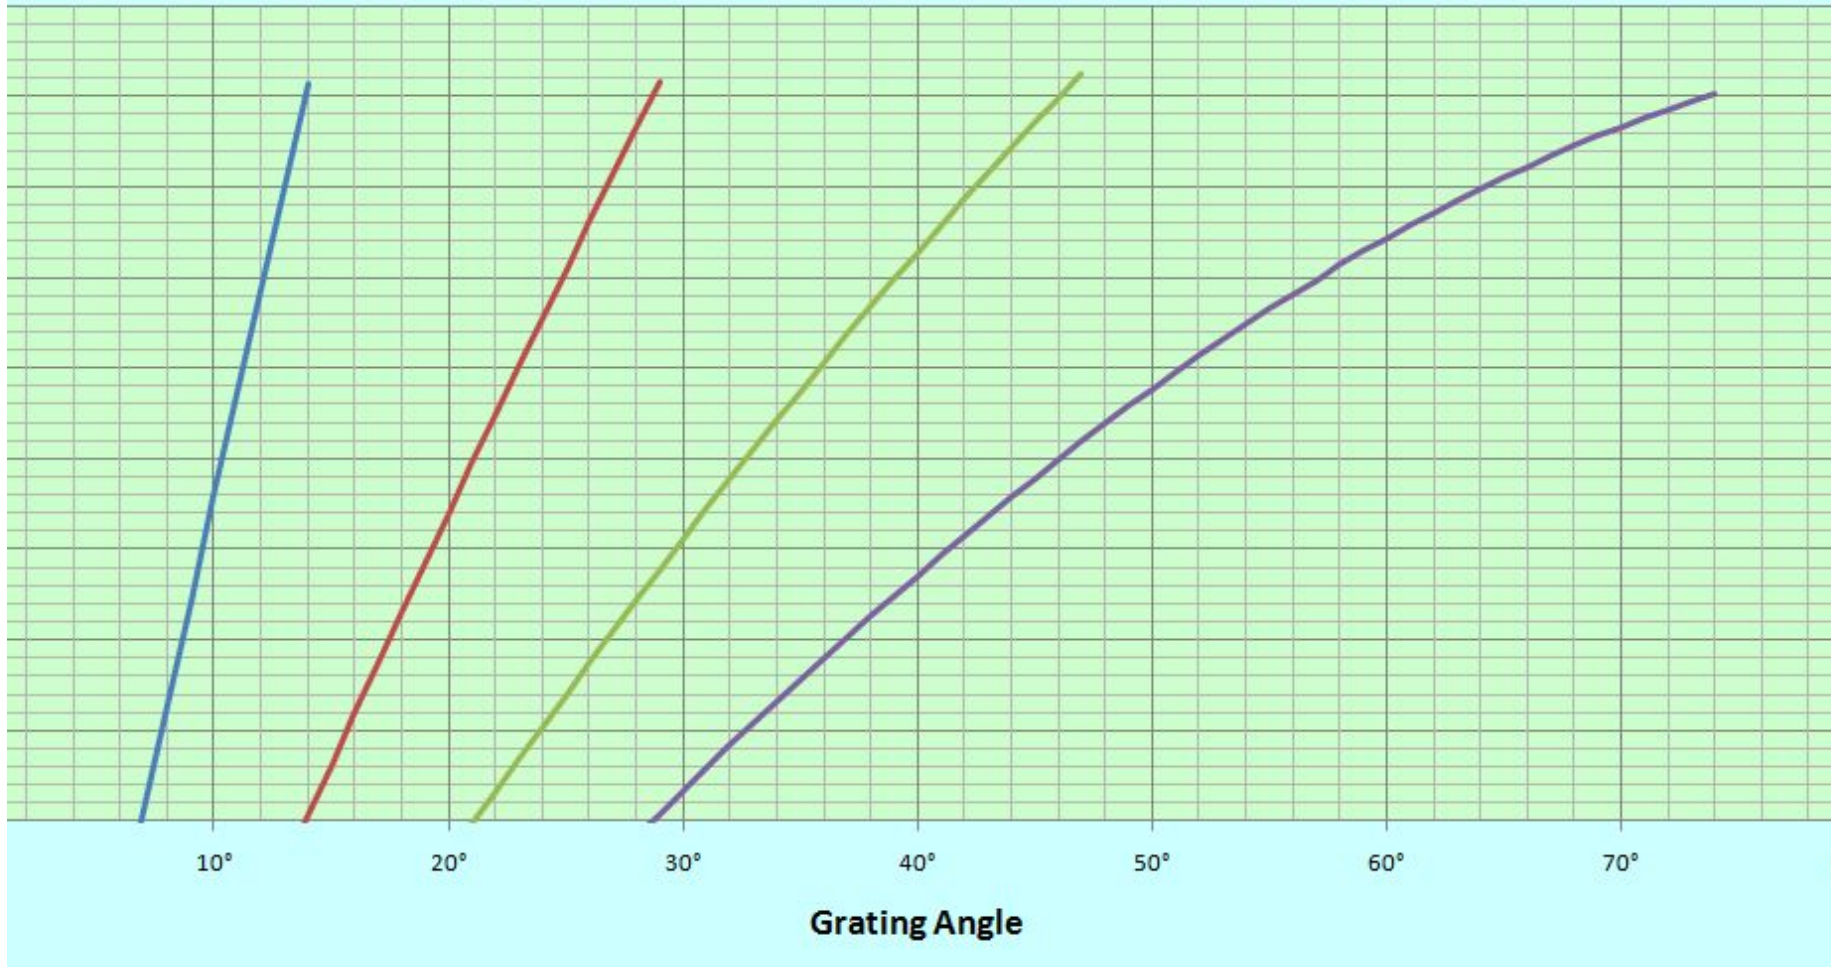

$$m\lambda = d(\sin \alpha + \sin \beta) = (m + 1)\lambda'$$

The **free spectral range** is the largest wavelength range for a given order that does not overlap the same range in an adjacent order.

$$\Delta\lambda_{free} = \lambda - \lambda' = \frac{\lambda}{m}$$

Overlapping Grating Orders

L200 Grating Angle Versus λ at 600L/mm Grating Orders 1, 2, 3 & 4

www.stargazing.net/david/spectroscopy/SpectralL200F4T5Dorders.html

Overlapping Orders

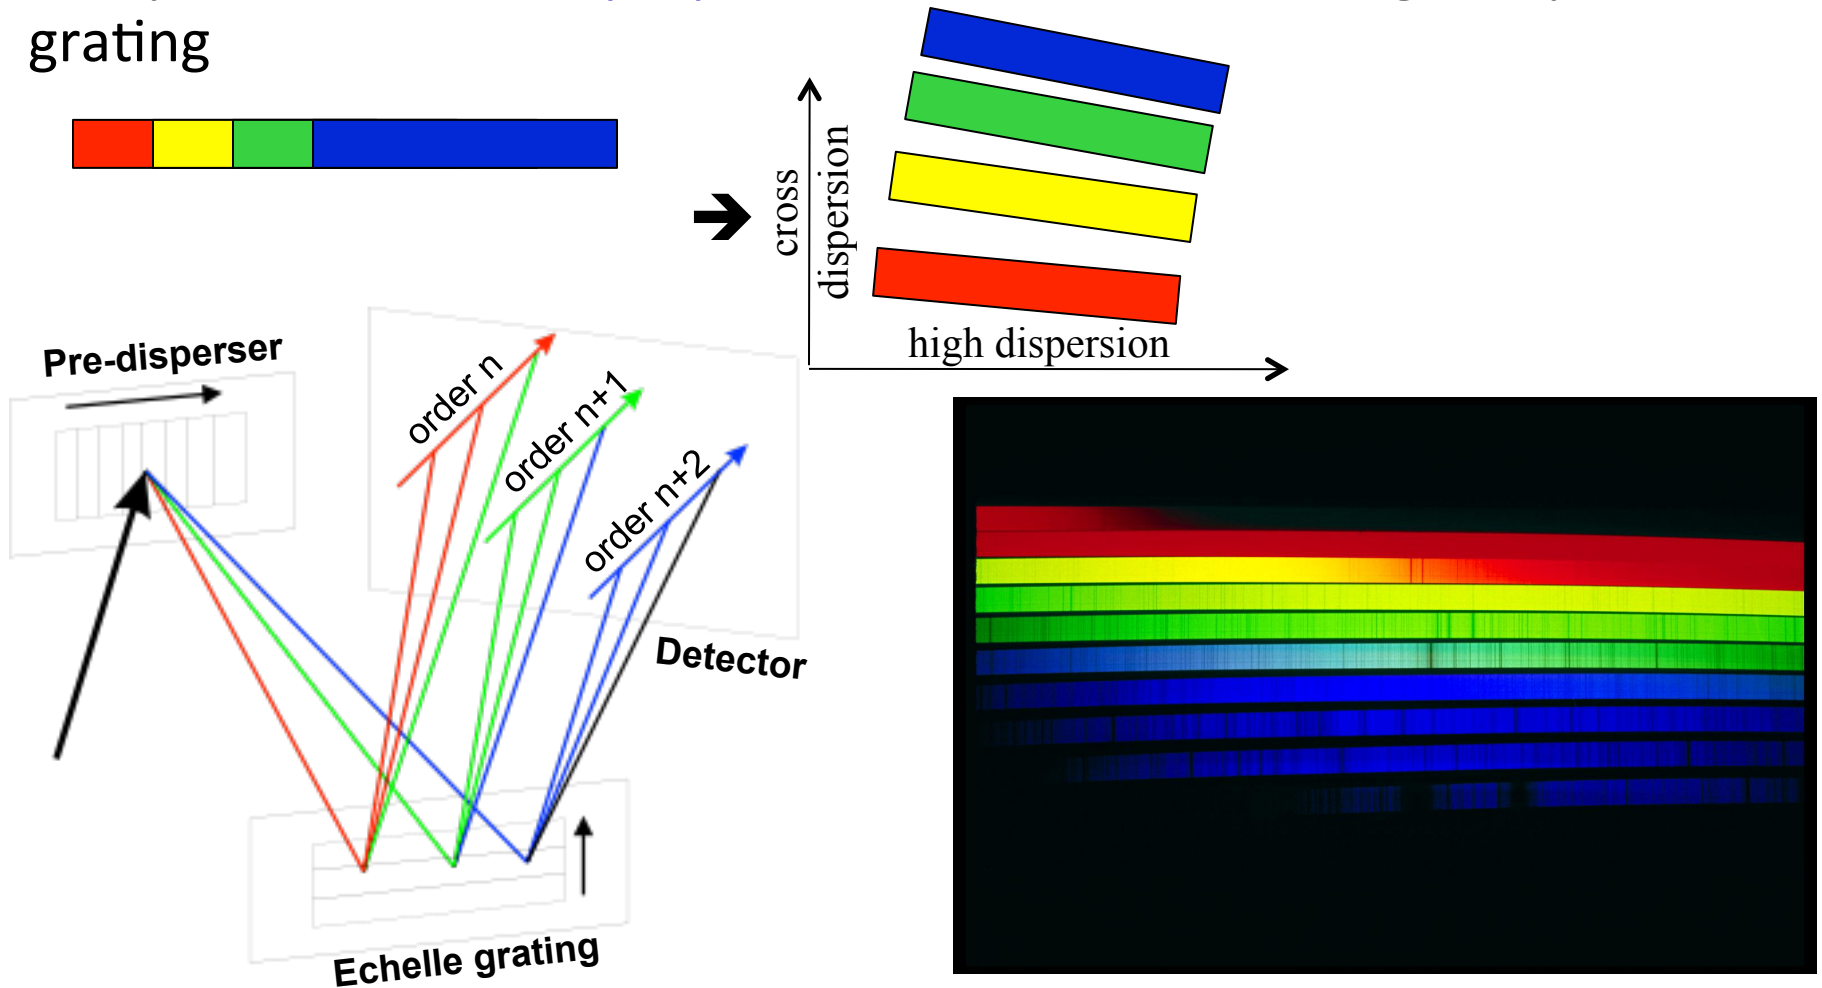

www.stargazing.net/david/spectroscopy/SpectraL200F4T5Dorders.html

- blue emission line in 3rd order overlaps red continuum in 2nd order

Cross-Dispersion

To spatially separate the orders and avoid overlap, an additional optical element will be needed: A low-dispersion prism/grating with a dispersion direction **perpendicular** to that of the high-dispersion grating

Echelle Gratings

Want high dispersion

$$\frac{d\beta}{d\lambda} = \frac{m}{d \cos \beta} = \frac{\sin \alpha + \sin \beta}{\lambda \cos \beta}$$

and high spectral resolution

$$R = Nm$$

α and β large, high order m (≈ 50), and therefore large a

Grating equation in Littrow configuration ($\alpha=\beta$): $m\lambda_B = 2d \sin\beta$

Echelle Spectrograph

Operation in high order \rightarrow cross-disperser essential

The Light Path of the High-Resolution Echelle Spectrograph

McMath-Pierce Spectrograph

Smaller Pixels

Echelle Spectrographs

Example: ESO's VLT instrument CRIRES:

The ruled echelle grating of the SOFIA Facility Spectrometer ARIES. Two images of the engineer are seen reflected from the facets of the grooves that are at angles of 90 degrees from each other.

Echelle Spectra

echelle spectrum of V454 Aur

Grisms

Grism = transmission GRating + prISM

For one wavelength and diffraction order, refraction of grating and prism may compensate and **optical axis remains (almost) unchanged.**

Advantages:

- ideal to bring in and out of a collimated beam (“filter wheel”)
- reduces coma (if in non-collimated beam)

Disadvantages:

- difficult to manufacture (replication and gluing or by direct ruling.)
- can be quite “bulky” (← filter wheel)

Interference (Transmission) Filters

Principle: layers with thickness of $\sim \lambda$ with different indices of refraction deposited on a substrate.

The transmission is maximal where
$$\frac{2n_1d}{\lambda} + \frac{\pi}{2} = 2k\pi$$

Refractive indices

$n_1(\lambda)$

$n_2(\lambda)$

- spectral resolution typically $R \sim 3 - 1000$
- typically many **interference layers**
- filters are often tilted with respect to the optical axis to avoid reflections \rightarrow shift of λ_0
- wavelengths farther from λ_0 (for which the above equation is also satisfied) need a blocking or **absorbing filter**.

Fabry-Perot Etalon

Two parallel plates (Fabry-Perot etalon) of high reflectivity r and transmission $t = 1-r$.

The transmission is:

$$I = I_0 \left(\frac{r}{1-r} \right)^2 \left[1 + \frac{4r}{(1-r)^2} \sin^2(2\pi dk \cos i) \right]^{-1}$$

and has transmission peaks where $k = \frac{m}{2d}$

Here, m is the **order** of the interferometer, d is the **separation** of the plates, and $\Delta k = 1/2d$ the **free spectral range**.

The spectral resolution is given by

1. The **fineness** $F = \frac{\pi\sqrt{r}}{1-r}$,

2. The **resolution** $R = \frac{k}{\Delta k} = mF$

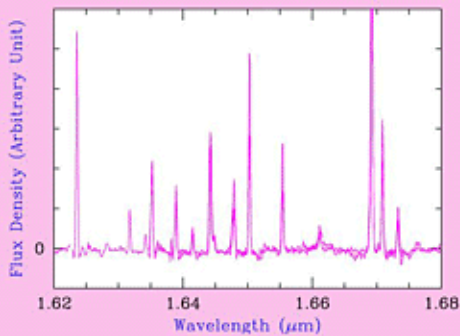

OH Suppression Spectrographs

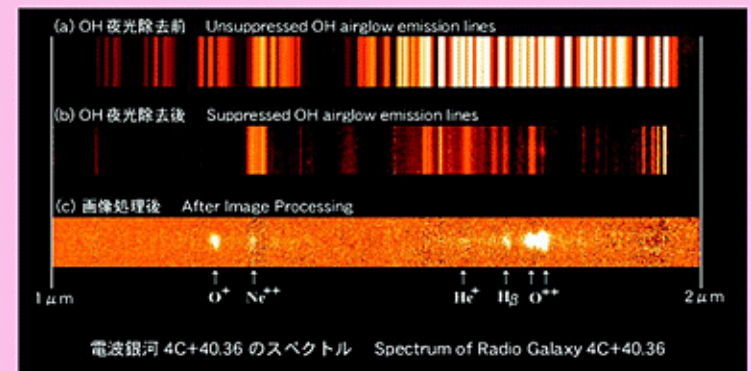

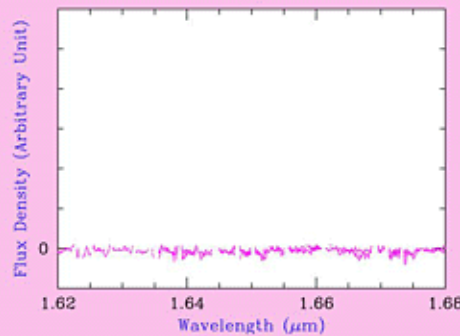

OHS filter out the wavelengths of atmospheric OH lines, which contribute the major part of the near-IR background.

Before Removing Night Lines

After Removing Night Lines

http://subarutelescope.org/Introduction/instrument/img/OHS_concept.gif

Multi-Object Spectrographs

Use numerous "slits" in the focal plane simultaneously → multiple source pick-ups using fibers or mirrors.

Needs different slit masks for different fields.

Hydra Arbitrary Fiber Positioning

Hydra Arbitrary Fiber Positioning

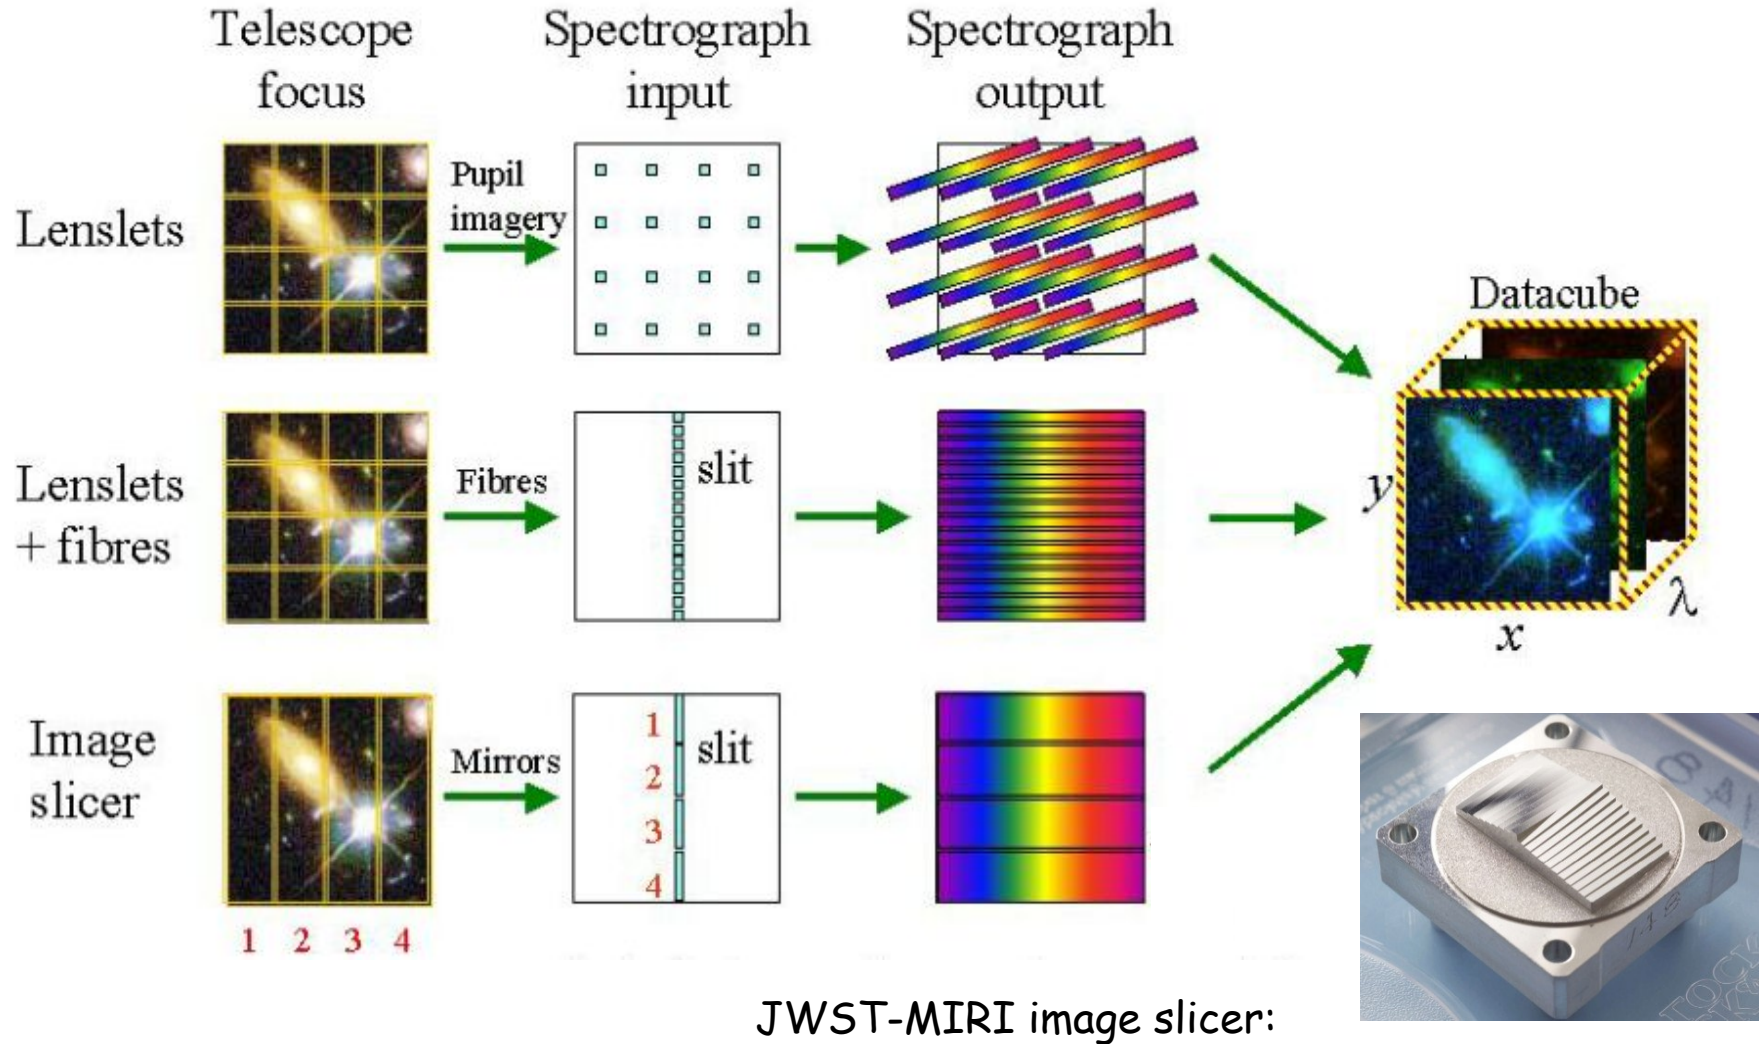

Multi-Object Spectrograph Spectra

Integral Field Spectrographs

Cut area on sky into adjacent slices or sub-portions, realign them optically into one long slice and treat it as a long slit spectrograph.

JWST-MIRI image slicer:

Leiden Observatory pIFU

Venus
(Rodenhuis
2013)

- 450-900 nm, $R \sim 25$
- polarization grating: polarizing beamsplitter and transmission grating

Simultaneous Multi-Wavelength Images of Venus

Fourier Transform Spectrometer (FTS)

- Assume a single pixel detector
- FTS or Michelson interferometer is a two-wave interferometer (grating has N waves from N grooves)

FTS – Measured Intensity

- Output intensity $I(x)$ for a **monochromatic** input intensity I_0 (with wave number $k=2\pi/\lambda$ and **path length difference** x) is:

$$I(x) = \frac{I_0}{2} (1 + \cos kx)$$

- Source with **spectrum** $I_0(k)$ in range $[k_1, k_2]$ produces signal

$$I(x) = \frac{1}{2} \int_{k_1}^{k_2} I_0(k) (1 + \cos kx) dk$$

- Constant term plus real part of Fourier transform of spectrum

FTS – Measured Intensity

- For each path-length difference x , all spectral elements of incident spectrum contribute to signal
- Only one Fourier component is measured at any given path-length difference x
- Spectral resolution with maximum path length difference x_{\max} is $R=2x_{\max}/\lambda$

FTS – Output Signal

- For each moving mirror position, broadband (integrated over wavelength) intensity is measured
- Measured signal is an **interferogram**
- Interferogram is Fourier transform of object spectrum

Pros & Cons of Different Spectrographs

Spectrometer	Advantages	Disadvantages
Long-slit	<ul style="list-style-type: none">• relatively simple → high throughput• easy to calibrate	<ul style="list-style-type: none">• only one object at a time• inefficient use of detector space
Echelle	<ul style="list-style-type: none">• high spectral resolution• efficient use of detector	<ul style="list-style-type: none">• challenging grating/optics• limited instantaneous λ range
Integral field	<ul style="list-style-type: none">• instantaneous 2D info• ideal for resolved objects	<ul style="list-style-type: none">• complex optics• single objects only
Multi-object	<ul style="list-style-type: none">• up to thousands of spectra• ideal for spectral surveys	<ul style="list-style-type: none">• complex mechanisms to select fields• fibre transmission limits λ
Fabry-Perot	<ul style="list-style-type: none">• ideal for large objects• high spectral resolution• more compact than FTS	<ul style="list-style-type: none">• not practical for large λ range• line and continuum observed at different times → calibration• needs pre-disperser
Fourier-transform (FTS)	<ul style="list-style-type: none">• very high resolution• absolute wavelengths• imaging FTS possible	<ul style="list-style-type: none">• less gain with high background• high resolution \Leftrightarrow wide interval• difficult in cryo instruments
