Signal or Noise?

SCUBA 850μm map of the Hubble deep field (Hughes et al. 1998, Nature volume 394, pages 241–247)
What is Noise? And what is real Signal?
Example 1: Digitization/Quantization Noise

- Analog-to-Digital Signal Converter (ADC).
- Number of bits determines dynamic range of ADC
- Resolution: 12 bit $2^{12} = 4096$ quantization levels
  16 bit $2^{16} = 65636$ quantization levels
- Discrete, “artificial” steps in signal levels $\rightarrow$ noise
Example 2: Read-out noise in CCDs

Probability

The Calculus of Probabilities is the mathematical theory which allows us to predict the statistical behaviour of complex systems from a basic set of fundamental axioms. Probabilities come in two distinct forms: discrete, where \( P_i \) is the probability of the \( i^{th} \) event occurring, and continuous, where \( P(x) \) is the probability that the even, or random variable, \( x \), occurs.

1. The Range of Probabilities: The probability of an event is measurable on a continuous scale, such that \( P(x) \) is a real number in the range \( 0 \leq P(x) \leq 1 \).

2. The Sum Rule: The sum of all discrete possibilities is

\[
\sum_i P_i = 1. \tag{1}
\]

For a continuous range of random variables, \( x \), this becomes

\[
\int_{-\infty}^{\infty} dx \, p(x) = 1, \tag{2}
\]

where \( p(x) \) is the probability density. The probability density clearly must have units of \( 1/x \).

Credits: https://www.roe.ac.uk/~ant/Teaching/Astronomical%20Stats/
Probability distributions can be characterized by their **moments**.

**Definition:**

\[ m_n \equiv \langle x^n \rangle = \int_{-\infty}^{\infty} dx \ x^n p(x), \]  

(6)  

is the \( n^{th} \) moment of a distribution. The angled brackets \( \langle \cdots \rangle \) denote the **expectation value**. Probability distributions are normalized so that

\[ m_0 = \int_{-\infty}^{\infty} dx \ p(x) = 1 \]  

(7)  

(Axiom 2, The Sum Rule).

The first moment,

\[ m_1 = \langle x \rangle, \]  

(8)  

gives the **expectation value** of \( x \), called the **mean**: the average or typical expected value of the random variable \( x \) if we make random drawings from the probability distribution.
Centred moments are obtained by shifting the origin of $x$ to the mean;

$$\mu_n \equiv \langle (x - \langle x \rangle)^n \rangle. \quad (9)$$

The second centred moment,

$$\mu_2 = \langle (x - \langle x \rangle)^2 \rangle, \quad (10)$$

is a measure of the spread of the distribution about the mean. This is such an important quantity it is often called the variance, and denoted

$$\sigma^2 \equiv \mu_2. \quad (11)$$

We will need the following, useful result later:

$$\sigma^2 = \langle (x - \langle x \rangle)^2 \rangle = \langle (x^2 - 2x\langle x \rangle + \langle x \rangle^2) \rangle = \langle x^2 \rangle - \langle x \rangle^2. \quad (12)$$

The variance is obtained from the mean of the square minus the square of the mean. Another commonly defined quantity is the square-root of the variance, called the standard deviation; $\sigma$. This quantity is sometimes also called the root mean squared (rms) deviation\(^3\), or error\(^4\).
Three Probability Density Functions

- Binomial distribution
- Poisson distribution
- Gaussian/normal distribution
The Binomial distribution allows us to calculate the probability, $P_n$, of $n$ successes arising after $N$ independent trials.

Suppose we have a sample of objects of which a probability, $p_1$, of having some attribute (such as a coin being heads-up) and a probability, $p_2 = 1 - p_1$ of not having this attribute (e.g. tails-up). Suppose we sample these objects twice, e.g. toss a coin 2 times, or toss 2 coins at once. The possible outcomes are hh, ht, th, and tt. As these are independent events we see that the probability of each distinguishable outcome is

$$P(hh) = P(h)P(h),$$
$$P(ht + th) = P(ht) + P(th) = 2P(h)P(t),$$
$$P(tt) = P(t)P(t).$$

(15)
These combinations are simply the coefficients of the binomial expansion of the quantity \((P(h) + P(t))^2\). In general, if we draw \(N\) objects, then the number of possible permutations which can result in \(n\) of them having some attribute is the \(n^{th}\) coefficient in the expansion of \((p_1 + p_2)^N\), the probability of each of these permutations is \(p_1^n p_2^{N-n}\), and the probability of \(n\) objects having some attribute is the binomial expansion

\[
P_n = C_n^N p_1^n p_2^{N-n}, \quad (0 \leq n \leq N),
\]  

where

\[
C_n^N = \frac{N!}{n!(N-n)!}
\]

are the Binomial coefficients. The binomial coefficients can here be viewed as statistical weights which allow for the number of possible indistinguishable permutations which lead to the same outcome. This distribution is called the general Binomial, or Bernoulli distribution. We can plot out the values of \(P_n\) for all the possible \(n\) (Figure 1) and in
Figure 1: Histogram of a binomial distribution

doing so have generated the predicted probability distribution which in this case is the binomial distribution whose form is determined by $N$, $n$, $p_1$. If we have only two possible outcomes $p_2 = 1 - p_1$. The Binomial distribution can be generalised to a multinomial distribution function.
The mean of the binomial distribution is

\[
\langle n \rangle = \sum_{n=0}^{N} nP
\]

\[
= \sum_{n=0}^{N} n \frac{N!}{n!(N-n)!} p_1^n p_2^{N-n}
\]

\[
= \sum_{n=1}^{N} \frac{N!}{(n-1)!(N-n)!} p_1^n p_2^{N-n}
\]

\[
= \sum_{n=1}^{N} \frac{N(N-1)!}{(n-1)!(N-n)!} p_1^{n-1} p_2^{N-n}
\]

\[
= Np_1
\]

For \( p_1 \neq p_2 \) the distribution is asymmetric, with mean \( \langle n \rangle = Np_1 \), but if is large the shape of the envelope around the maximum looks more and more symmetrical and tends towards a Gaussian distribution - an example of the Central Limit Theorem at work. More of this later!
1.5.2 The Poisson distribution

The **Poisson distribution** occupies a special place in probability and statistics, and hence in observational astronomy. It is the archetypal distribution for point processes. It is of particular importance in the **detection** of astronomical objects since it describes **photon noise**. It essentially models the distribution of randomly distributed, independent, point-like events, and is commonly taken as the null hypothesis.

It can be derived as a limiting form of the binomial distribution:

The probability of $n$ “successes” of an event of probability $p$ is

$$P_n = C_n^N p^n (1 - p)^{N-n} \quad (19)$$

after $N$ trials.

Let us suppose that the probability $p$ is very small, but that in our experiment we allow $N$ to become large, while keeping the mean finite, so that we have a reasonable chance of finding a finite number of successes $n$. That is we define $\lambda = \langle n \rangle = Np$ and let $p \to 0$, $N \to \infty$, while $\lambda =$constant. Then,

$$P_n = \frac{N!}{n!(N-n)!} \left( \frac{\lambda}{N} \right)^n \left( 1 - \frac{\lambda}{N} \right)^{N-n} \quad (20)$$
Using Stirling’s approximation, where $x! \rightarrow \sqrt{2\pi e^{-x}x^{x+1/2}}$ when $x \rightarrow \infty$, and letting $N \rightarrow \infty$, we find\textsuperscript{5}

$$P_n = \frac{\lambda^n e^{-\lambda}}{n!}$$

(24)

This is Poisson’s distribution for random point processes, discovered by him in 1837.
1.5.3 Moments of the Poisson distribution:

Let's look at the moments of the Poisson distribution:

\[ m_i = \langle n^i \rangle = \sum_{n=0}^{\infty} n^i P_n \]  \hspace{1cm} (25)

The mean of Poisson's distribution is

\[
\langle n \rangle = \sum_{n=0}^{\infty} n \frac{\lambda^n e^{-\lambda}}{n!} \\
= \sum_{n=1}^{\infty} \frac{\lambda^n e^{-\lambda}}{(n-1)!} \\
= \sum_{n=1}^{\infty} \frac{\lambda \lambda^{n-1} e^{-\lambda}}{(n-1)!} \\
= \lambda 
\]  \hspace{1cm} (26)

i.e. the expectation value of Poisson's distribution is the factor \( \lambda \). This makes sense since \( \lambda \) was defined as the mean of the underlying Binomial distribution, and kept constant when we took the limit. Now let's look at the second centred moment (i.e. the variance):
when we took the limit. Now let's look at the second centred moment (i.e. the variance):

\[
\mu_2 = \sum_{n=0}^{\infty} (n - \langle n \rangle)^2 \frac{\lambda^n e^{-\lambda}}{n!}
\]

\[
= \sum_{n=0}^{\infty} n^2 \frac{\lambda^n e^{-\lambda}}{n!} - \lambda^2
\]

\[
= \sum_{n=1}^{\infty} \frac{n\lambda^n e^{-\lambda}}{(n-1)!} - \lambda^2
\]

\[
= \sum_{n=1}^{\infty} \frac{n\lambda \lambda^{n-1} e^{-\lambda}}{(n-1)!} - \lambda^2
\]

\[
= \sum_{n=0}^{\infty} \frac{(n+1)\lambda \lambda^n e^{-\lambda}}{n!} - \lambda^2
\]

\[
= (\lambda + 1)\lambda - \lambda^2
\]

\[
= \lambda.
\]  

(27)

So the variance of Poisson's distribution is also \(\lambda\). **This means that the variance of the Poisson distribution is equal to its mean.** This is a very useful result.
Poisson distribution

\[ P_n = \frac{\lambda^n e^{-\lambda}}{n!} \]

- \( n \): number of occurrences of an event
- \( \lambda \): expected (average) number of occurrences, hence the mean of \( P_n \) is \( \lambda \)
- variance of \( P_n \) is \( \lambda \)
- standard deviation of \( P_n \) is square root of \( \lambda \)
Poisson PDF

\[
P(X=k) = \frac{e^{-\lambda} \lambda^k}{k!}
\]

- **\( \lambda = 1 \)**
- **\( \lambda = 4 \)**
- **\( \lambda = 10 \)**
Poisson Cumulative Distribution Function

The graph shows the Poisson cumulative distribution function for different values of $\lambda$: $\lambda = 1$, $\lambda = 4$, and $\lambda = 10$. The function is plotted against $k$, the number of occurrences, and the cumulative probability $P(X \leq k)$. The plot visualizes how the cumulative probability increases with $k$ for each value of $\lambda$. The graph demonstrates the characteristic shape of the Poisson distribution with different intensities determined by $\lambda$. 
Poisson Noise

• Poisson noise has Poisson distribution

• probability of number of events occurring in constant interval of time/space if events occur with known *average rate* and *independently* of each other

• example: fluctuations in photon flux in finite time intervals $\Delta t$: chance to detect $k$ photons with average flux of $\lambda$ photons
1.5.4 A rule of thumb

Let's see how useful this result is. When counting photons, if the expected number detected is \( n \), the variance of the detected number is \( n \): i.e. we expect typically to detect

\[
 n \pm \sqrt{n} \tag{28}
\]

photons. Hence, just by detecting \( n \) counts, we can immediately say that the uncertainty on that measurement is \( \pm \sqrt{n} \), without knowing anything else about the problem, and only assuming the counts are random. This is a very useful result, but beware: when stating an uncertainty like this we are assuming the underlying distribution is Gaussian (see later). Only for large \( n \) does the Poisson distribution look Gaussian (the Central Limit Theorem at work again), and we can assume the uncertainty \( \sigma = \sqrt{n} \).
1.5.5 Detection of a Source

A star produces a large number, $N \gg 1$, of photons during its life. If we observe it with a telescope on Earth we can only intercept a tiny fraction, $p \ll 1$, of the photons which are emitted in all directions by the star, and if we collect those photons for a few minutes or hours we will collect only a tiny fraction of those emitted throughout the life of the star.

So if the star emits $N$ photons in total and we collect a fraction, $p$, of those, then
\[
\lambda = Np
\]
\[
N \to \infty
\]
\[
p \to 0.
\]

So if we make many identical observations of the star and plot out the frequency distribution of the numbers of photons collected each time, we expect to see a Poisson distribution.
Conversely, if we make one observation and detect $n$ photons, we can use the Poisson distribution to derive the probability of all the possible values of $\lambda$: we can set confidence limits on the value of $\lambda$ from this observation. And if we can show that one piece of sky has only a small probability of having a value of $\lambda$ as low as the surrounding sky, then we can say that we have detected a star, quasar, galaxy or whatever at a particular **significance level** (i.e. at a given probability that we have made a mistake due to the random fluctuations in the arrival rate of photons). A useful rule of thumb here is

$$\lambda_S \geq \lambda_B + \nu \sqrt{\lambda_B}$$

(30)

where $\lambda_S$ is the mean counts from the source, $\lambda_B$, is the mean background count, and $\nu$ is the detection level. Usually we take $\nu = 3$ to be a detection, but sometimes it can be $\nu = 5$ or even $\nu = 15$ for high confidence in a detection.
1.6.1 The Gaussian Distribution

A limiting form of the Poisson distribution is the Gaussian distribution.

\[ p(x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{(x-m)^2}{2s^2}} \]
Normal/Gaussian PDF

\[ \varphi_{\mu, \sigma^2}(x) \]

- \( \mu = 0, \ \sigma^2 = 0.2, \)
- \( \mu = 0, \ \sigma^2 = 1.0, \)
- \( \mu = 0, \ \sigma^2 = 5.0, \)
- \( \mu = -2, \ \sigma^2 = 0.5, \)
Normal Cumulative Distribution

\[ \Phi_{\mu, \sigma^2}(x) \]

- \( \mu = 0, \ \sigma^2 = 0.2, \)
- \( \mu = 0, \ \sigma^2 = 1.0, \)
- \( \mu = 0, \ \sigma^2 = 5.0, \)
- \( \mu = -2, \ \sigma^2 = 0.5, \)
Gaussian Noise

- **Gaussian noise** has Gaussian (normal) distribution
- Sometimes (incorrectly) called **white noise** (uncorrelated noise)

\[ S = \frac{1}{\sqrt{2\pi \sigma}} \exp \left[ -\frac{(x - \mu)^2}{2\sigma^2} \right] \]

- \( x \): actual value
- \( \mu \): mean of distribution
- \( \sigma \): standard deviation of distribution

1-\( \sigma \) ~ 68%
2-\( \sigma \) ~ 95%
3-\( \sigma \) ~ 99.7%

Astronomers often consider \( S/N > 3\sigma \) or > 5\( \sigma \) as significant
Scientists Like Gauss

• Reasons to like Gaussian distribution:
  – variances of independent Gaussian distributions add
  – Poisson distribution approximates Gaussian for large numbers
  – combinations of different distributions tend to lead to Gaussian distribution

• Always check whether the distribution is Gaussian
Signal or Noise?
Signal or Noise?
Correct Statistics?
Noise Measurement

If purely Gauss or Poisson noise distribution, no other systematic noise and no correlations,

then the spatial distribution (neighbouring pixels) of the noise is equivalent to the temporal distribution (successive measurements with one pixel)

This is analogous to throwing 5 dices once versus throwing one dice

Case 1: Spatial noise (detector pixels)  Case 2: Repeated measurements in time (time series)  Case 3: Spectrum (dispersed information)
Poisson Noise and Integration Time

• Integrate light from uniform, extended source on detector
• In finite time interval $\Delta t$, expect average of $\lambda$ photons
• Statistical nature of photon arrival rate $\Rightarrow$ some pixels will detect more, some less than $\lambda$ photons.
• Noise of average signal $\lambda$ (i.e., between pixels) is $\sqrt{\lambda}$
• Integrate for $2\times\Delta t \Rightarrow$ expect average of $2\times\lambda$ photons
• Noise of that signal is now $\sqrt{2\lambda}$, i.e., increased by $\sqrt{2}$
• With respect to integration time $t$, noise will only increase $\sim\sqrt{t}$ while signal increases $\sim t$
Signal-to-Noise Ratio: Infrared Imaging

• Measurement:
  – signal (in #photons) from source plus background (in #photons) towards source

• $<B>$: average sky background (# photons) from source area

• $\text{SNR} = \frac{S}{N} = \frac{(S + B - <B>)}{\sqrt{<B>}}$
Assuming the signal suffers from **Poisson shot noise**. Let’s calculate the dependence on integration time $t_{\text{int}}$:

**Integrating $t_{\text{int}}$:**

$$\sigma = \frac{S}{N}$$

**Integrating $n \times t_{\text{int}}$:**

$$\sigma = \frac{n \cdot S}{\sqrt{n \cdot B}} \overset{N=\sqrt{B}}{=} \sqrt{n} \cdot \frac{S}{N} \quad \Rightarrow \quad \frac{S}{N} \propto \sqrt{t_{\text{int}}}$$

*Need to integrate four times as long to double the SNR*
**SNR Dependence on Source**

**Background (=noise)**  
Target

---

**Seeing-limited point source**
- pixel size ~ seeing
- PSF ≠ f(D)

**Diffraction-limited, extended source**
- pixel size ~ diff.lim
- PSF = f(D)
- target >> PSF

**Diffraction-limited, point source**
- pixel size ~ diff.lim
- PSF = f(D)
- target << PSF

(D: diameter telescope)
Case 1: Seeing-limited “Point Source”

Signal* = S; Background* = B; Noise = N; Telescope diameter = D

θ_{seeing} \sim \text{const}

If detector is Nyquist-sampled to θ_{seeing}:

\begin{align*}
S & \sim D^2 \quad \text{(area)} \\
B & \sim D^2 \rightarrow N \sim D \quad \text{(Poisson std.dev)} \\
\Rightarrow S/N & \sim D \\
\Rightarrow t_{\text{int}} & \sim D^{-2}
\end{align*}

*per pixel
**Case 2: Diffraction-limited extended Source**

Signal* = S;  Background* = B;  Noise = N;  Telescope diameter = D

“Diameter” of PSF ~ const

If detector Nyquist sampled to $\theta_{\text{diff}}$: pixel ~ $D^{-2}$ but $S \sim D^2$

$D^2$ (telescope size) and $D^{-2}$ (pixel FOV) cancel each other $\rightarrow$ no change in signal

same for the background flux

$\rightarrow$ $S/N \sim \text{const} \rightarrow t_{\text{int}} \sim \text{const}$

$\rightarrow$ *no gain for larger telescopes!*

Note:

Total signal / Noise = $\sim D^2/\sim \sqrt{D^2} \sim D$
Case 3: Diffraction-limited “Point Source”

Signal* = S; Background* = B; Noise = N; Telescope diameter = D

“\(S/N = (S/N)_{\text{light bucket}} \cdot (S/N)_{\text{pixel scale}}\)”

(i) Effect of telescope aperture: \(\rightarrow S/N \sim D\)
- Signal \(S \sim D^2\)
- Background \(B \sim D^2 \rightarrow N \sim D\)

(ii) Effect of pixel FOV (if Nyquist sampled to \(\theta_{\text{diff}}\)): \(\rightarrow S/N \sim D\)
- \(S \sim \text{const} \) (pixel samples PSF = all source flux)
- \(B \sim D^{-2} \rightarrow N \sim D^{-1}\)

(i) and (ii) combined \(S/N \sim D^2 \rightarrow t_{\text{int}} \sim D^{-4}\)

\(\rightarrow \text{huge gain: 1hr ELT} = 3 \text{ months VLT}\)
Instrument Sensitivity Example: HAWK-I

http://www.eso.org/observing/etc/bin/ut4/hawki/script/hawkisimu

Input Flux Distribution

- **Uniform (constant with wavelength)**
  - NOTE: Please use the "Uniform" template spectrum instead of this option.
  - Template Spectrum: ADV (Pickles) (9480 K)
  - Redshift z = 0.00

- **Blackbody**
  - Temperature = 15000.00 K

- **Single Line**
  - Lambda = 1250.000 nm
  - Flux = $5.00 \times 10^{-16}$ ergs/s/cm² (per arcsec² for extended sources)
  - FWHM = 1.000 nm

Spatial Distribution:
- **Point Source**
- **Extended Source** diameter: 1.00 arcsec
- **Extended Source (per pixel)**

The Magnitude (or flux) is given per arcsec² for extended sources.

Sky Conditions

- **Airmass:** 1.20
- **Seeing:** 0.80 arcsec (FWHM in V band)

Instrument Setup

- **Filter:** K
- **Detector mode:** Non-destructive Read-out (NDR)

Results

- **S/N ratio:** $S/N = 100,000$
- **Exposure Time:** NDIT = 100 sec, DIT = 60,000 sec

with data from ETC
\[ \sigma = \frac{S_{el}}{N_{tot}} \]

- detected signal
- total noise
- number of pixels
- background noise
  - background flux
  - read noise
  - dark current
- intensity
- pixel FOV

Instrument Sensitivity: Example
Detected Signal

Detected signal $S_{el}$ depends on:

- source flux density $S_{src}$ [photons s$^{-1}$ cm$^{-2}$ μm$^{-1}$]
- Strehl ratio $SR$ (ratio of actual to theoretical maximum intensity)
- spectral bandwidth $\Delta \lambda$ [μm]
- telescope aperture $A_{tel}$ [m$^2$]
- detector responsivity $\eta_{DG}$
- transmission of the atmosphere $\eta_{atm}$
- total throughput of the system $\eta_{tot}$, which includes:
  - reflectivity of all telescope mirrors
  - reflectivity (or transmission) of all instrument components, such as mirrors, lenses, filters, beam splitters, grating efficiencies, slit losses, etc.
- integration time $t_{int}$ [s]

$$S_{el} = S_{src} \cdot SR \cdot \Delta \lambda \cdot A_{tel} \cdot \eta_{DG} \cdot \eta_{atm} \cdot \eta_{tot} \cdot t_{int}$$
Total Noise

Total noise $N_{\text{tot}}$ depends on:

- number of pixels $n_{\text{pix}}$ of one resolution element
- background noise per pixel $N_{\text{back}}$

\[ N_{\text{tot}} = N_{\text{back}} \sqrt{n_{\text{pix}}} \]

Total background noise $N_{\text{back}}$ depends on:

- background flux density $S_{\text{back}}$
- integration time $t_{\text{int}}$
- detector dark current $I_d$
- pixel read-out noise ($N_{\text{read}}$) and detector frames ($n$)

\[ N_{\text{back}} = \sqrt{S_{\text{back}} \cdot t_{\text{int}} + I_d \cdot t_{\text{int}} + N_{\text{read}}^2 \cdot n} \]
Background Flux Density $S_{\text{back}}$

depends on:

- total background intensity $B_{\text{tot}} = (B_T + B_A) \cdot \eta_{\text{tot}}$
  $B_T, B_A$ are thermal emissions from telescope and atmosphere (\sim black body)

- pixel size and field of view: $A \times \Omega$

- detector responsivity: $\eta_D G$

- spectral bandwidth: $\Delta \lambda$

\[
S_{\text{back}} = B_{\text{tot}} \cdot A \times \Omega \cdot \eta_D G \cdot \Delta \lambda
\]
Putting it all together, the total signal to noise ratio for a given experiment is:

\[
\sigma = \frac{S_{el}}{N_{tot}} = \frac{S_{src} \cdot SR \cdot \Delta \lambda \cdot A_{tel} \cdot \eta_D G \cdot \eta_{atm} \cdot \eta_{tot} \cdot t_{int}}{N_{back} \sqrt{n_{pix}}}
\]

\[
\Rightarrow S_{src} = \sigma \cdot \sqrt{S_{back} \cdot t_{int} + I_d \cdot t_{int} + N^2_{read} \cdot n \cdot \sqrt{n_{pix}}} \]

\[
\frac{SR \cdot \Delta \lambda \cdot A_{tel} \cdot \eta_D G \cdot \eta_{atm} \cdot \eta_{tot} \cdot t_{int}}{SR \cdot \Delta \lambda \cdot A_{tel} \cdot \eta_D G \cdot \eta_{atm} \cdot \eta_{tot} \cdot t_{int}}
\]
Noise Propagation: Example

- ratio of two spectral lines as a function of depth of one of the spectral lines
- noise of ratio strongly changes with line depth
- noise affects average ratio

![Graphs showing observed and simulated magnetic line ratio at Δλ_f = -40 mÅ](image)
Noise Propagation

• same as error propagation
• function \( f(u,v,\ldots) \) depends on variables \( u,v,\ldots \)
• estimate variance of \( f \) knowing variances \( \sigma_u^2, \sigma_v^2, \ldots \) of variables \( u,v,\ldots \)

\[
\sigma_f^2 = \frac{1}{N-1} \lim_{N \to \infty} \sum_{i=1}^{N} (f_i - \bar{f})^2
\]

• make assumption / approximation that average of \( f \) is well approximated by value of \( f \) for averages of variables: \( \bar{f} = f(\bar{u}, \bar{v}, \ldots) \)
Noise Propagation (cont.)

• Taylor expansion of $f$ around average:

$$f_i = \bar{f} \square (u_i \quad \bar{u}) \frac{f}{u} + (v_i \quad \bar{v}) \frac{f}{v} + \ldots$$

• variance in $f$:

$$f^2 \square \lim_{N \to \infty} \sum_{i=1}^{N} \left[ (u_i \quad \bar{u}) \frac{\partial f}{\partial u} + (v_i \quad \bar{v}) \frac{\partial f}{\partial v} + \ldots \right]^2$$

$$= \lim_{N \to \infty} \sum_{i=1}^{N} \left[ (u_i \quad \bar{u})^2 \left( \frac{\partial f}{\partial u} \right)^2 + (v_i \quad \bar{v})^2 \left( \frac{\partial f}{\partial v} \right)^2 + 2(u_i \quad \bar{u})(v_i \quad \bar{v}) \frac{\partial f}{\partial u} \frac{\partial f}{\partial v} + \ldots \right]$$
Noise Propagation (cont.)

• variances of $u$ and $v$

$$u^2 \equiv \lim_{N \to \infty} \sum_{i=1}^{N} (u_i - \bar{u})^2; \quad v^2 \equiv \lim_{N \to \infty} \sum_{i=1}^{N} (v_i - \bar{v})^2$$

• covariance of $u$ and $v$ (*can be negative!*)

$$u v^2 \equiv \lim_{N \to \infty} \sum_{i=1}^{N} (u_i - \bar{u})(v_i - \bar{v})$$

• combine Taylor expansion and these definitions

$$f^2 = u^2 \left( \frac{\partial f}{\partial u} \right)^2 + v^2 \left( \frac{\partial f}{\partial v} \right)^2 + 2 u v \left( \frac{\partial f}{\partial u} \frac{\partial f}{\partial v} \right) +$$
Noise Propagation (cont.)

• from before

\[ f^2 = u^2 \left( \frac{\partial f}{\partial u} \right)^2 + v^2 \left( \frac{\partial f}{\partial v} \right)^2 + 2 \ u \ v \ \frac{\partial f}{\partial u} \ \frac{\partial f}{\partial v} + \]

• if differences \((u_i - \bar{u})\) and \((v_i - \bar{v})\) not correlated \(\Rightarrow\) sign of product as often positive as negative \(\Rightarrow\) covariance small compared to other terms

• if differences are correlated \(\Rightarrow\) most products \((u_i - \bar{u})(v_i - \bar{v})\) have the same sign \(\Rightarrow\) cross-correlation term can be large
